1 Introduction

2 Degenerative lumbar scoliosis (DLS) is one of the most difficult clinical conditions to
3 understand in the lumbar spinal disorders because its pathology and mechanism have not been
4 fully elucidated. Deformity in DLS is primarily based on wedge disc deformity in a coronal
5 plane; however, it has been considered to accompany axial rotation. Coexistence of the wedge
6 and axial rotational deformity has been reported as one of the relevant factors of progression of
7 the spinal deformity.¹ Currently, the various corrective instrumentation procedures have been
8 performed even for highly degenerative scoliosis. However, indication and clinical results of
9 corrective surgery for such three-dimensional (3D) deformity have been controversial.²

10 Although importance of axial rotational deformity in DLS has been recognized, limited
11 information on the segmental axial rotational angles in the DLS patients is available in the
12 literature. The axial rotational deformity has been typically determined by means of evaluating
13 positions of pedicles projected on plain radiograms.³ Because of 3D nature of the spinal
14 deformity in DLS, it is difficult to accurately measure rotational angles about three anatomical
15 axes using two-dimensional (2D) image data.

16 In recent years, lateral lumbar interbody fusion (LLIF) has been applied for restoration
17 of the disc height, correction of deformity and stabilization for DLS and its usefulness has been
18 reported.⁴⁻⁶ The LLIF procedure is a minimally invasive procedure in preserving anterior and
19 posterior longitudinal ligaments intact. In the LLIF procedure, restoration of disc height causes
20 tensioning of the anterior and posterior longitudinal ligaments, which is called “ligamentotaxis”
21 and has been considered to provide posterior neural decompression, correction of spinal
22 alignment and stabilization of the motion segment. Although some studies have addressed disc
23 height restoration and deformity correction by LLIF, correlation between the disc height and the
24 amount of deformity correction has not been analyzed in a quantitative manner.^{4,5}

1
2
3
4
5 25 The aim of the present study is two-fold; first, to quantitate segmental rotational
6
7 26 deformities in 3D and to clarify correlations between the rotational angles about three anatomical
8
9
10 27 axes in patients with lumbar degenerative disease, and second, to evaluate the effect of LLIF
11
12 28 procedure on correction of 3D deformity using patient-specific 3D-CT models.
13

14 29

16 30 **Material and Methods**

18 31 *Subject Selection*

19 31
20
21 32 The study group included 28 subjects with lumbar degenerative disease (14 subjects with L3/4
22
23 33 and 14 with L4/5 affected), including spondylosis, degenerative scoliosis, and degenerative
24
25 34 spondylolisthesis, in whom LLIF was performed to relieve the neuropathy (e.g., pain, gait
26
27 35 disturbance) and low back pain at our institution from June 2014 to July 2016 (Table 1). Patients
28
29 36 with correction surgery for adult spinal deformity with low back pain only were excluded. LLIF
30
31 37 was performed to achieve correction and nerve decompression. After undergoing LLIF using
32
33 38 eXtreme lumbar interbody fusion (XLIF) cage (XLIF®; NuVasive Inc., California, USA) in the
34
35 39 lateral position, the posterior side was stabilized with in situ percutaneous pedicle screws (PPS)
36
37 40 in the prone position. PPS insertion was performed without any accompanying corrective
38
39 41 procedure (e.g., posterior osteotomy, compression, distraction manipulation). This study was
40
41 42 approved by the hospital's ethics committee.
42
43 43

44 43 *Imaging Studies*

45 44 Each subject underwent CT imaging (CT machine: SOMATOM Definition AS+®; SIEMENS
46
47 45 Healthineers Inc., JAPAN, tube voltage: 120 kV, tube current: approximately 120 mAs, field of
48
49 46 view: approximately 250 × 180 mm, image matrix: 512 × 512, slice increment: 5 mm, slice
50
51 47 thickness: 5 mm) in a supine position preoperatively and three months after surgery. 3D vertebral
52
53 48 models of the lumbar spine were created using 3D reconstruction software (Mimics®;
54
55
56
57
58
59
60
61
62
63
64
65

49 Materialise Inc., Leuven, Belgium). In the postoperative 3D vertebral models, pedicle screws and
50 intervertebral cages were excluded from the models.

51 *3D Alignment Analyses*

52 Posterior wall models were created from the vertebral models for 3D alignment analyses.

53 Eigenvectors of each posterior wall were calculated to determine 3D orientation of the posterior
54 wall. A Cartesian (X-Y-Z) local coordinate system was set on each posterior wall in which an
55 origin was set on a centroid of the posterior wall and orientation was determined by the
56 eigenvectors. The X, Y and Z axes corresponded to mediolateral, posteroanterior and
57 craniocaudal axes, respectively. The coronal (XZ) plane, sagittal (YZ) plane, and transverse
58 (XY) plane were defined from these X-Y-Z axes. The rotations of the superior vertebral body
59 relative to the inferior vertebral body in the adjacent two vertebral bodies were expressed using
60 Eulerian angles in a transverse plane-sagittal plane-coronal plane (Z-X-Y) sequence. The wedge
61 angle, lordosis angle and axial rotation angle were defined by the Eulerian angles in the coronal
62 plane, sagittal plane and axial plane, respectively. A positive value of the lordosis angle was
63 defined as lordosis and the negative value as kyphosis (Figure 1A, 1B).

64 *Disc height measurement*

65 Three-dimensional disc height distribution was measured by the least distances between each
66 point of the lower bony endplate of the superior vertebral body and the superior bony endplate of
67 the inferior vertebral body and the mean value of the least distances was determined as the disc
68 height (Figure 1C).⁷

69 *Spinopelvic parameter measurement*

70 The Cobb angle was measured on a standing anteroposterior radiographic image. Lumbar
71 lordosis (LL), thoracic kyphosis (TK), sagittal vertical axis (SVA), sacral slope (SS), pelvic tilt
72 (PT), and pelvic incidence (PI) were measured on standing lateral radiographic images.

73 *Statistical Analyses*

74 The rotational angles, disc heights, and spinopelvic parameters measured preoperatively and
75 postoperatively were compared by paired *t*-tests. Correction rates of these values due to surgery
76 were calculated by $|\text{preoperative value} - \text{postoperative value}|/\text{preoperative value}$. For the
77 correlation between the two groups, Pearson's correlation coefficient and a *t*-test were used.
78 Statistical significance was defined as $P < 0.05$. The results were shown as mean \pm standard
79 deviation (SD).

81 **Results**

82 *Correlations between the rotational angles (before LLIF)*

83 A strong positive correlation was found between the wedge angle and the axial rotation angle (r
84 = 0.718, $P < 0.001$) in the patients with lumbar degenerative disease preoperatively (Figure 2).

85 *Effect of LLIF procedure on correction of 3D segmental deformities*

86 The wedge angle decreased after surgery ($P < 0.001$) from the preoperative value of $8.4^\circ \pm 5.4^\circ$
87 (range: $0.8^\circ - 25.6^\circ$) to the postoperative value of $3.8^\circ \pm 3.1^\circ$ (range: $0^\circ - 9.7^\circ$) by a correction
88 rate of 55% ($-4.6^\circ \pm 3.5^\circ$). The lordosis angle increased after surgery ($P < 0.01$) from the
89 preoperative value of $5.7^\circ \pm 5.3^\circ$ (range: -7.3° to 17.5°) to the postoperative value of $7.8^\circ \pm 5.2^\circ$
90 (range: -1.1° to 17.2°) by a correction rate of 37% ($+2.1^\circ \pm 4.0^\circ$). The axial rotation angle
91 decreased after surgery ($P < 0.001$) from the preoperative value of $5.9^\circ \pm 4.2^\circ$ (range: $0.7^\circ - 21.1^\circ$)
92 to the postoperative value of $3.8^\circ \pm 3.4^\circ$ (range: $0.1^\circ - 13.7^\circ$) by a correction rate of 35% ($-2.1^\circ \pm$
93 5.0°) (Figure 3).

94 The disc height increased after surgery ($P < 0.001$) from the preoperative value of $5.4 \pm$
95 1.5 mm (range: 2.7 - 8.1 mm) to the postoperative value of 9.3 ± 1.4 mm (range: 7.3 - 12.8 mm)
96 by a correction rate of 72% (3.9 ± 1.6 mm) (Figure 3).

97 A positive correlation was found between the wedge angle and the axial rotation angle
98 ($r = 0.46$, $P < 0.001$, Figure 4).

99 *Effect of LLIF procedure on correction of global deformities*

100 The Cobb angle decreased after surgery ($P = 0.035$) from the preoperative value of $15.2^\circ \pm 9.7^\circ$
101 (range 2° – 40°) to the postoperative value of $11.6^\circ \pm 9.1^\circ$ (range 0° – 37°). The LL increased after
102 surgery ($P = 0.041$) from the preoperative value of $27.7^\circ \pm 18.8^\circ$ (range -7° to 60°) to the
103 postoperative value of $34.4^\circ \pm 17.5^\circ$ (range -6° to 68°). The SVA decreased after surgery ($P <$
104 0.01) from the preoperative value of 72.6 ± 57.8 mm (range -7.5 to 40 mm) to the postoperative
105 value of 42.1 ± 37.8 mm (range -15.9 to 166.1 mm). The PI-LL decreased after surgery ($P =$
106 0.017) from the preoperative value of $22.6^\circ \pm 16.3^\circ$ (range -8° to 62°) to the postoperative value
107 of $15.5^\circ \pm 15.3^\circ$ (range -13° to 52°) (Table 2).

109 **Representative case**

110 The patient complained of right lower extremity pain before surgery. We diagnosed L4/5 right
111 foraminal stenosis and performed LLIF. The wedge angle decreased after surgery from the
112 preoperative value of 11.3° to the postoperative value of 4.8° (correction rate 58%). The lordosis
113 angle increased after surgery from the preoperative value of 1.3° to the postoperative value of
114 5.9° (correction rate 354%). The axial rotation angle decreased after surgery from the
115 preoperative value of 13° to the postoperative value of 9.5° (correction rate 27%). The disc
116 height increased after surgery from the preoperative value of 4.3 mm to the postoperative value
117 of 10.5 mm (correction rate 144%) (Figure 5). Postoperatively, the right leg pain was alleviated.

119 **Discussion**

120 The present study demonstrated that the strong correlations between the wedge angle and the

1
2
3
4
5 121 axial rotation angle existed in the patients with lumbar degenerative disease and the LLIF
6
7 122 procedure restored the disc height and corrected 3D deformities in three anatomical planes using
8
9 123 the patient-specific 3D-CT models created by preoperative and postoperative CT scanning. The
10
11 124 3D analyses of the lumbar alignment allowed accurate quantitative measurements of 3D
12
13
14 125 rotational deformities in the patients with lumbar degenerative disease and the correction of these
15
16 126 rotational deformities by the LLIF which is difficult to measure in the two-dimensional plane
17
18
19 127 radiograms.
20

21 128 Longitudinal studies to look at progression of the spinal deformity by evaluating Cobb
22
23
24 129 angle and rotational deformity by such as Nash and Moe's method which determined the grade
25
26 130 (0 to IV) reported that Cobb angle increased by more than 10 ° in grade II and III cases in
27
28
29 131 patients with adult spinal deformity who had follow-up for at least 10 years. ³ These studies
30
31 132 indicated that the axial rotation is one of the relevant factors of progression of the DLS patients. ⁸
32
33 133 ⁹ Korovessis et al. and Ferrero et al. stated that intervertebral disc space asymmetry that occurs,
34
35
36 134 followed by rotatory subluxation, including intervertebral lateral slip and rotation, causes *de*
37
38 135 *novo* degenerative scoliosis as the 3D deformity mechanism of the spine. ^{10, 11} It is possible that
39
40
41 136 the deformity of the vertebral bodies, the form of the facet joints, the angle of the cage, the
42
43 137 position of cage after insertion, the shape of the adjacent intervertebral space, and osteoporosis,
44
45 138 among other factors, might be related. ^{12, 13} The quantitative 3D analysis on the segmental axial
46
47
48 139 rotation using patient-specific 3D models shown in the present study would provide more
49
50 140 accurate prediction of future progression of the spinal deformity in DLS. Future longitudinal
51
52
53 141 studies will be warranted to demonstrate the benefit of this technology.
54

55 142 Surgical correction of the combined wedge and rotational deformity is important for
56
57 143 improving clinical symptoms derived from intervertebral foramina and spinal canal stenosis.
58
59
60 144 Wiktor et al. reported that they obtained 29.3% rotational correction of DLS by direct vertebral
61
62
63
64
65

1
2
3
4
5 145 rotation method using pedicle screws and corrective connection devices,¹⁴ but we could find no
6
7 146 reports of rotation correction with LLIF. In the present study, we achieved rotational correction
8
9 147 of 35% with the LLIF procedure. It should be noted that intentional correction of the axial
10
11
12 148 rotation from the posterior side or dissociated facet joints was not performed in the present study.
13

14 149 In this study, not only was the local lordosis angle increased by LLIF but the global
15
16 deformity was affected. The LL increased, and the SVA and PI-LL decreased, with the increase
17 150
18
19 151 in LL large relative to the increase in the local lordosis angle. These improvements in sagittal
20
21 152 parameters are unlikely to be the result of local anatomical changes alone. We surmised that they
22
23
24 153 came close to the patient's original posture because the back and leg pain was relieved. The
25
26 154 Cobb angle in the coronal plane was also corrected, correlated with the parallel reduction of a
27
28
29 155 single intervertebral disc space. These alterations in the global alignment would produce better
30
31 156 clinical results along with the local effects of the single-level correction.
32

33 157 The present study showed the positive correlation between the wedge correction angle
34
35
36 158 and the axial rotation correction angle. Interestingly, this correlation is similar to the correlation
37
38 159 between wedge deformation angle and axial rotation deformation angle shown preoperatively
39
40
41 160 with the similar correlation equation. Because only distraction force was applied to restore the
42
43 161 disc height and no external torque was applied to correct the axial rotation in the present study,
44
45 162 wedge and axial rotational movements during progression of deformity or correction procedure
46
47
48 163 can be described as a "coupled motion."
49

50 164 The coupled motion in lumbar lateral bending has been observed in several studies.¹⁵⁻¹⁷
51
52
53 165 In lateral bending, the inferior articular process glides superior direction in reference to the
54
55 166 superior articular process of the inferior vertebra on the convex side of the spinal curve and
56
57 167 opposite direction on the concave side.¹⁸ Schendel et al. reported that lateral bending motion was
58
59
60 168 coupled with axial rotation (i.e. left lateral bending was associated with axial rotation which
61
62
63
64
65

1
2
3
4
5 169 loads the right facet) and the facet resultant contact force location in left lateral bending was in
6
7 170 the same area as that for right axial torsion.¹⁵ The authors suggested that the axial rotation
8
9
10 171 component associated with lateral bending could be partially responsible for facet loading.¹⁵
11
12 172 During correction of the wedge deformity, spinal ligamentotaxis by anterior and posterior
13
14 173 longitudinal ligaments may also contribute to the coupled motion.^{19, 20}
15

16
17 174 There are some limitations in our study. We did not evaluate the installation position of
18
19 175 the XLIF cage. The position of the cage could affect not only the lordosis angle but also the
20
21 176 wedge angle and axial rotation angle. The CT scans used for postoperative evaluation in our
22
23
24 177 study were obtained after both the cage and PPS had been inserted. Therefore, the contribution of
25
26 178 correction achieved by in situ PPS fixation cannot be ignored. Because we did not consider facet
27
28
29 179 degeneration, disc degeneration, segmental stiffness, or size or distribution of osteophytes, it is
30
31 180 unclear whether the correction effect will be reproducible when this procedure is performed on
32
33 181 other patients.
34

35
36 182 Future studies on 3D geometry and kinematics of the facet joint will be needed to
37
38 183 understand the wedge and axial rotational coupled deformation in the patients with lumbar
39
40 184 degenerative disease and the coupling effects in correction of the 3D deformities. Evaluation of
41
42
43 185 deformity and/or dislocation of the facet joint may also be needed to predict the reduction effects
44
45 186 of the LLIF in the future studies.
46

47
48 187

49 50 188 **Conclusion**

51
52 189 The present study demonstrated positive correlations between the wedge deformity and the axial
53
54
55 190 rotational deformity in 28 patients with lumbar degenerative disease who underwent LLIF
56
57 191 surgery using patient-specific 3D-CT models. The axial rotational deformity was simultaneously
58
59
60 192 corrected with LLIF only by leveling the intervertebral wedge deformity via cage insertion. The
61
62
63
64
65

1
2
3
4
5 193 coupled motion caused by the facet joint and ligamentotaxis may contribute to achieve
6
7 194 intervertebral correction of both wedge and axial rotational deformities only by inserting a cage
8
9 195 during LLIF; however, future studies will be required to understand mechanisms of the coupling
10
11 196 effects in correction of the 3D deformities by LLIF.

16 in the adjacent two vertebral bodies were expressed using Eulerian angles. The
17
18 wedge angle, lordosis angle and axial rotation angle were defined by them in the
19
20 coronal plane, sagittal plane and axial plane, respectively.
21
22
23 C) Three-dimensional disc height distribution was measured by the least distances
24
25 between each point of the lower bony endplate of the superior vertebral body and
26
27 the superior bony endplate of the inferior vertebral body and the mean value of
28
29 the least distances was determined as the disc height.
30
31
32
33
34
35

Figure 2

36
37 A strong positive correlation was found between the wedge angle and the axial rotation
38
39 angle ($r = 0.718$, $P < 0.001$) in the patients with lumbar degenerative disease
40
41 preoperatively.
42

8

9
10 Figure 5.

11
12 These are standing anteroposterior and lateral radiographic images before and after
13
14 surgery in the representative case. The disc height and the lordosis angle increased,
15
16 while the wedge and axial rotation angles decreased after LLIF. The Cobb angle and PI-
17
18 LL decreased, while the LL increased.

Disclosure of potential conflicts of interest

Authors must disclose all relationships or interests that could have direct or potential influence or impart bias on the work. Although an author may not feel there is any conflict, disclosure of all relationships and interests provides a more complete and transparent process, leading to an accurate and objective assessment of the work. Awareness of real or perceived conflicts of interest is a perspective to which the readers are entitled. This is not meant to imply that a financial relationship with an organization that sponsored the research or compensation received for consultancy work is inappropriate. For examples of potential conflicts of interests *that are directly or indirectly related to the research please visit:*

<http://www.springer.com/gp/authors-editors/journal-author/journal-author-helpdesk/publishing-ethics/14214>

All authors of papers submitted to European Spine Journal
[include name of journal] must complete this form and disclose any real or perceived conflict of interest.

Please complete one form per author. The corresponding author collects the conflict of interest disclosure forms from all authors. The corresponding author will include a summary statement that reflects what is recorded in the potential conflict of interest disclosure form(s). Please check the Instructions for Authors where to put the statement which may be different dependent on the type of peer review used for the journal. Please note that you cannot save the form once completed. Please print upon completion, sign, and scan to keep a copy for your files.

The corresponding author should be prepared to send potential conflict of interest disclosure form if requested during peer review or after publication on behalf of all authors (if applicable).

I have no potential conflict of interest.

Category of disclosure	Description of Interest/Arrangement

Article title Coupling Effects in Correction of Three-dimensional Deformity
in Degenerative Lumbar Scoliosis by Lateral Lumbar Interbody Fusion

Manuscript No. (if you know it) _____

Author name Hiroto Yamaguchi

Are you the corresponding author? Yes No

Herewith I confirm that the information provided is accurate.

Author signature Hiroto Yamaguchi Date April 21, 2019
